I. INTRODUCTION

About 70 000 pictures of  $2.45\text{-GeV}/c$   $K^-p$  interactions have been obtained in the present 72-inch hydrogen bubble-chamber experiment.<sup>1</sup> Approximately 24 000 events of all topologies except 1-, 2-, and 3-prong events have been measured, and 50% have been remeasured. We report here on a study of the production of known resonances in the reactions:

$$K^- + p \rightarrow \Lambda + \pi^+ + \pi^- \quad (1)$$

$$K^- + p \rightarrow \Lambda + \pi^+ + \pi^0 + \pi^- \quad (2)$$

The cross section for production and number of events in reactions (1) and (2) are given in Table I.

II.  $Y_1^*(1385)$  AND  $\rho$  PRODUCTION IN THE REACTION  $K^-p \rightarrow \Lambda \pi^+ \pi^-$

To estimate the amount of resonance production, we have assumed no interference between production of  $Y_1^{*+}$ ,  $Y_1^{*-}$ ,  $\rho^0$ , or background. We constructed a likelihood function, assuming phase space for the nonresonant background and a matrix element proportional to  $[(M - M_0)^2 + (\Gamma/2)^2]^{-1}$  for each resonant process, independent of any alignment. Masses and widths

\*Work done under the auspices of the U. S. Atomic Energy Commission.

used in calculation of the likelihood function are given in Table II. The fit corresponding to the maximum likelihood is shown in Fig. 1 as a solid curve over histograms of the mass distribution of the events. In the  $\Lambda\pi^-$  mass distribution the curve has been modified to take account of the nonisotropic decay of  $Y_1^{*+}$  with respect to its line of flight in the overall center of mass. We also show phase space, normalized to the total number of events, for comparison. The percentages of this final state contributed by each process are given in Table III. Even though interference may be important in further analysis of this final state, the mass distributions clearly do not give much information on this interference.

Figure 2 is a plot of the angular distribution in production of the three resonant states. We have defined a  $Y_1^*$  band as  $\Lambda\pi$  invariant mass between 1.335 and 1.435  $\text{GeV}/c^2$  and a  $\rho$  band as  $\pi^+\pi^-$  mass between 0.665 and 0.865  $\text{GeV}/c^2$  for selection of events to be included in angular distributions. For the  $Y_1^*$  production, Fig. 2a and b, the solid histogram corresponds to the angular distribution of those  $Y_1^*$  events that are not also in the  $\rho$  band. The dotted histogram is an estimate of the angular distribution for all  $Y_1^*$ ; the contribution of events within the  $\rho$  band is estimated from  $Y_1^*$  events outside the  $\rho$  band that, upon a parity reversal of the  $Y_1^*$  in its center of mass, become events in the  $\rho$  band. This technique of treating the  $Y^*-\rho$  overlap region is described in reference 2.

In Fig. 2c, the solid histogram corresponds to all events in the  $\rho$  band. The dotted curve is an estimate of the angular distribution for  $\rho$  production arrived at by subtraction of background estimated by parity reversal of  $\Lambda\pi$  events. This procedure is equivalent to assuming phase space for the non- $Y_1^*$  events.

At this momentum the  $Y_1^{*+}$  and  $Y_1^{*-}$  angular distributions are markedly different from one another, and both distributions differ from previously reported angular distributions for the same states at lower momenta.<sup>3</sup> The  $\rho$  production angular distribution, after background subtraction is statistically very weak, and the forward peak is not statistically significant.

### III. $Y_1^*$ , $\rho$ AND $\omega$ PRODUCTION IN THE REACTION $K^-p \rightarrow \Lambda \pi^+ \pi^0 \pi^-$

The effective-mass plots of this final state show significant evidence for the production of  $Y_1^*$ ,  $\rho$ , and  $\omega$ . Other resonant production occurs, but the rate of production is significantly lower than it is for these resonances. Again assuming (unjustifiably) noninterference of various resonant states and background, we have constructed a likelihood function similar to the one described in Section II for the eleven processes:

$$K^-p \rightarrow \Lambda \omega$$

$$Y_1^{*+} \rho^-$$

$$Y_1^{*0} \rho^0$$

$$Y_1^{*-} \rho^+$$

$$Y_1^{*+} \pi^0 \pi^-$$

$$Y_1^{*0} \pi^+ \pi^-$$

$$Y_1^{*-} \pi^+ \pi^0$$

$$\Lambda \pi^- \rho^+$$

$$\Lambda \pi^0 \rho^0$$

$$\Lambda \pi^+ \rho^-$$

$$\Lambda \pi^+ \pi^0 \pi^-$$

The masses and widths used in calculating the likelihood function are given in Table IV. The likelihood fits are not very sensitive to the widths used for the resonances; we find that 20% changes in the widths change the solutions by less than half a standard deviation. Table V gives the maximum likelihood

solution for percentages of the final state contributed by each process. Figure 3 contains mass plots for the two particle masses and the  $3\pi$  system. Monte Carlo events were generated for each process. The solid curves of Fig. 3 are obtained from the Monte Carlo events by weighting each event in proportion to the appropriate percentage in Table III. Phase space normalized to the total number of events is shown as a dashed line in Fig. 3.

The  $\pi$ - $\pi$  mass distributions at low  $\pi$ - $\pi$  mass get a large contribution from the  $\omega$  events ( $\sim 300$ ). For these events it was necessary to take account of the decay matrix element of the  $\omega$  which sharpens the distribution of  $\pi$ - $\pi$  masses.

The resonant production cross sections for  $Y_1^*$  and  $\omega$  are about two times those reported by Bertanza et al. at this conference two years ago for  $K^-$  interactions at 2.24 GeV/c.<sup>4</sup> Their numbers were preliminary and based on 247  $\Lambda\pi^+\pi^0\pi^-$  events; so there is no real discrepancy.

Figure 4 gives the angular distribution in production of the  $Y_1^*\rho$  and  $\Lambda\omega$  events. If an event happened to fall in the overlap region of two  $Y_1^*\rho$  charge combinations, it is not included in the angular distribution. There is no  $Y_1^*\rho$ - $\Lambda\omega$  overlap. The  $\Lambda\omega$  angular distribution is given with the  $Y_1^*$  events removed (solid curve) and with them included (dotted curve).

The  $Y_1^*\rho$  and  $\Lambda\omega$  angular distributions indicate that all kinematically allowed momentum transfers are involved in the production processes. The  $Y_1^{*+}\rho^-$  events show a peaking at low momentum transfer, which may be due to the presence of an additional peripheral process. There is no significant change in the  $\Lambda\omega$  angular distribution from that reported at 2.24 GeV/c by Bertanza et al.<sup>4</sup>

#### IV. CONCLUSION

We have determined the production cross section for the processes given in Tables III and V and angular distributions for the most copiously produced pseudo-two-body final states. It will be interesting to continue this procedure throughout the 2.0- to 2.8-GeV/c  $K^-$  momentum range for many final states

and try to relate the production cross sections by means of SU3 for different processes. For instance, the  $Y_1^* \rho$  production should be related to the  $\Xi^*(1530) K^*(888)$  production, since in each case we have a member of the well-known baryon decuplet and a member of the well-known vector-meson octet. At 2.45 GeV/c, the beam is below threshold for  $\Xi^* K^*$  production; however, at 2.6 and 2.7 GeV/c  $\Xi^* K^*$  production occurs. <sup>5</sup>

Table I. Cross sections and numbers of events for

$$K^-p \rightarrow \Lambda \pi^+ \pi^- \text{ and } K^-p \rightarrow \Lambda \pi^+ \pi^0 \pi^-.$$

Reaction	Number of events	Cross section <sup>a</sup> (mb)
$K^-p \rightarrow \Lambda \pi^+ \pi^-$	576	$0.68 \pm 0.04$
$K^-p \rightarrow \Lambda \pi^+ \pi^0 \pi^-$	1508	$1.78 \pm 0.07$

a. Corrected for neutral  $\Lambda$  decay.

Table II. Masses and widths used in likelihood  
calculations for  $K^- p \rightarrow \Lambda \pi^+ \pi^-$ .

Resonance	Mass (GeV)	Width, $\Gamma$ (GeV)
$Y_1^{*+}$	1.385	0.05
$Y_1^{*-}$	1.385	0.05
$\rho^0$	0.765	0.12

Table III. Maximum-likelihood solution for final-state contributions for each process for  $K^- p \rightarrow \Lambda \pi^+ \pi^-$ .

Reaction	Percent
$K^- p \rightarrow \Lambda \rho^0$	$21.8 \pm 3.7$
$K^- p \rightarrow Y^{*+} \pi^-$	$19.1 \pm 2.3$
$K^- p \rightarrow Y^{*-} \pi^+$	$8.7 \pm 1.9$
"Phase space"	$50.4 \pm 4.1$

Table IV. Masses and widths used in likelihood calculations for  $K^- p \rightarrow \Lambda \pi^+ \pi^0 \pi^-$ .

Resonance	Mass (GeV)	Width, $\Gamma$ (GeV)
$Y^{*+}$	1.385	0.05
$Y^{*-}$	1.385	0.05
$Y^{*0}$	1.385	0.05
$\rho^+$	0.750	0.120
$\rho^-$	0.750	0.120
$\rho^0$	0.765	0.120
$\omega$	0.782	0.035

Table V. Maximum-likelihood solution for final-state contributions for each process for  $K^- p \rightarrow \Lambda \pi^+ \pi^0 \pi^-$ .

Reaction	Percent
$K^- p \rightarrow \Lambda \omega$	$21.5 \pm 1.4$
$K^- p \rightarrow Y^{*+} \rho^-$	$12.0 \pm 2.2$
$K^- p \rightarrow Y^{*0} \rho^0$	$5.0 \pm 1.9$
$K^- p \rightarrow Y^{*-} \rho^+$	$10.7 \pm 2.1$
$K^- p \rightarrow Y^{*+} \pi^0 \pi^-$	$6.4 \pm 2.3$
$K^- p \rightarrow Y^{*0} \pi^+ \pi^-$	$8.5 \pm 2.2$
$K^- p \rightarrow Y^{*-} \pi^+ \pi^0$	$4.7 \pm 2.3$
$K^- p \rightarrow \Lambda \pi^- \rho^+$	$0(-1.9) \pm 2.4$
$K^- p \rightarrow \Lambda \pi^0 \rho^0$	$3.8 \pm 2.1$
$K^- p \rightarrow \Lambda \pi^+ \rho^-$	$3.4 \pm 2.5$
"Phase space"	$25.8 \pm 4.8$
